(54) Title: A SUPERABSORBENT FIBRE OR NONWOVEN MATERIAL, A METHOD FOR ITS MANUFACTURE, AND AN ABSORBENT ARTICLE COMPRISING THE SUPERABSORBENT FIBRE OR NONWOVEN MATERIAL			
(57) Abstract			
Superabsorbent fibres or nonwoven material comprising a thermoplastic polymeric fibre to which solid particles of superabsorbent material have been thermo-bonded by heating the polymeric fibre to a temperature at which adhesion is obtained between fibres and particles. The invention also relates to an absorbent article, such as a diaper, sanitary napkin, incontinence guard and the like which includes such super-absorbent fibres or nonwoven material, optionally in combination with other fibres, such as cellulose fibres.

A superabsorbent fibre or nonwoven material, a method for its manufacture, and an absorbent article comprising the superabsorbent fibre or nonwoven material

Technical Field

The present invention relates to superabsorbent fibres or nonwoven materials in which particles of superabsorbent material 5 have been bonded to individual fibres. The invention also relates to a method of producing the superabsorbent fibres or nonwoven material concerned, and to absorbent articles that contain the same.

10 Background art

It is known to admix particles of water-insoluble hydrogels, so-called superabsorbents, in fibre structures for absorption purposes, for instance absorbent bodies in diapers, sanitary 15 napkins, incontinence guards, wound dressings etc. These superabsorbents are polymeric materials that are capable of absorbing large quantities of liquid. One problem encountered when mixing superabsorbents in fibre structures is to fix the superabsorbent particles in the structure so as to localize the superabsorbent 20 in the correct position in the product, and so that the product can be handled in manufacture and during transportation without the superabsorbent being redistributed in the product or shaken from the fibre structure. Dusting caused by fine-grain superabsorbents can also lead to an environmental problem at the place 25 of manufacture.

Several methods of adhering superabsorbent to fibres are known to the art. According to one method described in US-A-4,354,487 and EP-A-0,402,650, a monomeric solution is allowed to infiltrate 30 a fibre network or is mixed with free fibres. The monomers are then allowed to polymerize in place on the fibres. Prior publication US-A-4,888,238 describes a method in which dissolved polyelectrolytes form complex bonds on the fibres. According to another method, described in US-A-4,128,692, fibres are first suspended 35 in water and the superabsorbent is then added and

precipitates onto the fibres. In all of the aforesaid cases it is necessary to evaporate-off the solvent, i.e. the water, in one way or another, after having bound the superabsorbent to the fibres. This is difficult to achieve when the water is bonded 5 firmly to the superabsorbent.

According to another method, described in US-A-4,721,647, a water-soluble monomer having double bonds is allowed to form droplets around a hydrophobic fibre, these droplets being 10 allowed to polymerize and form cross-links. The underlying concept is that the superabsorbent shall embrace the fibre so as not to be released when absorbing liquid. According to the measurements reported in said Patent Specification, less than 20% by weight of the superabsorbents are released in the process 15 of absorption. It is also mentioned in the Patent Specification that the absorbent droplets should not be applied too densely, since this would stiffen the fibres.

Another method of adhering superabsorbents to fibres is de- 20 scribed in WO 90/11181 and WO 91/10413, according to which fibres are coated with a binder which binds to superabsorbent particles. The binder may consist of an ethylene vinyl acetate copolymer, ethylene acrylic acid copolymer, polyvinyl chloride or some other thermosetting resin, for instance. The binder is 25 sprayed onto the fibres a number of times, so as to effectively cover the fibre surfaces. Absorbent grains are then applied to the fibres before the binder has set. Between 15 and 50 % by weight of the absorbents, based on the dry fibre weight, are bonded when practicing this method, which is about equal to the 30 amount of superabsorbents that is effectively bonded when practicing the other methods aforesaid.

US-A-5,002,814 discloses another solution to the problem, in which a particle of a superabsorbent polymer has been bound to 35 several short fibres.

The object of the present invention and its most important characteristics

- 1 The object of the present invention is to bind superabsorbent
5 particles to fibres so that distribution of the superabsorbents
in a fibre structure can be better controlled. Adhesion between
superabsorbent and fibre should preferably be relatively low, so
as not to limit to any great extent the swelling space that is
available to the superabsorbents when absorbing liquid. Binding
10 of the superabsorbent particles to the fibres shall also be ef-
fected without the aid of a solvent that must later be eva-
porated off, and also while avoiding the application of binder
to the fibre.
- 15 This object has been achieved in accordance with the invention
in that the fibre or at least a part of the fibres present in
the nonwoven material is comprised of a thermoplastic polymer
fibre to which solid particles of superabsorbent material have
been thermobonded by heating said fibre to a temperature at
20 which adhesion between fibre and particles is achieved.

Synthetic fibres may be fully crystalline, i.e. contain 100% crystalline material, although they may alternatively contain varying percentages of crystalline material. A high degree of
25 stretching in connection with manufacturing the fibre will produce a high proportion of crystalline material. Partially crystalline fibres (0-40%) are preferably used in accordance with the invention, such fibres providing good adhesion at low temperatures. One speaks about the softening temperature or
30 glass transition temperature (T_g) in the case of amorphous fibres.

In the case of fibres that are part crystalline and part amorphous, the amorphous material

35 will be soft at temperatures between the softening temperature and the crystalline melting point, whereas the crystalline material will still be hard. There is thus obtained a certain degree of adhesion, which improves, however, when the crystalline melting point is exceeded.

When the thermoplastic fibre consists of a crystalline or partly crystalline fibre, the crystalline melting point of the fibre will suitably not be higher than 300°C, and preferably not higher than 270°C. When the thermoplastic fibre is an amorphous 5 fibre, its softening or glass transition temperature will preferably not be higher than 100°C.

The fibre may be comprised, for instance, of a polyolefin, such as polyethylene or polypropylene, polyester, polyamide, bicomponent fibre, or a copolymer of ethylene and acrylic/methacrylic acid or ethylene and vinyl acetate. 10

The superabsorbent particles will suitably have a mean particle size of up to 500 µm. 15

The invention also relates to a method of producing the superabsorbent fibre or nonwoven material concerned, this method being characterized by bringing solid particles of superabsorbent material into contact with a thermoplastic polymeric fibre or a 20 nonwoven material which includes thermoplastic polymeric fibres, said fibre being heated or having been heated to a temperature at which the superabsorbent particle adheres to the fibre, and thereafter allowing the mixture to cool.

The invention also relates to an absorbent article, such as a diaper, sanitary napkin, incontinence guard and the like, which is characterized in that the article has at least one absorbent layer which includes superabsorbent fibres or nonwoven material according to the invention, optionally in combination with other 25 fibres, such as cellulose fibres. 30

Brief description of the drawings

The invention will now be described in more detail with reference to exemplifying embodiments thereof and also with reference to the accompanying drawings, in which 35 Figures 1 and 2 are enlarged photographic views of a fibre to which superabsorbent particles of different size fractions have been bonded;

Figure 3 is an absorption curve from a demand wetting test; Figures 4-7 are photographs of an inventive fibre during different stages of an absorption process; and Figures 8 and 9 are schematic longitudinal section views of an absorbent body included in an absorbent article, such as a diaper, sanitary napkin, incontinence guard or the like.

Description of exemplifying embodiments

10 Synthetic fibres comprised of two different polymers have been used in the following tests, the one being an ethylene acrylic acid copolymer, EAA, containing 5.7 mol-% acrylic acid, and the other being an ethylene vinyl acetate copolymer, EVA, containing 3.1 mol-% vinyl acetate. The crystalline melting point of the 15 EAA-polymer was about 94°C, and in the case of the EVA-polymer about 97°C. The fibres each had a length of about 1 cm and the EAA-fibre had a thickness of 21 dtex and the EVA-fibre had a thickness of 11 dtex. The superabsorbent polymer used was Nippon-Shokubais Aqualic CA W3, which is a sodium salt of open-20 structure cross-linked polyacrylic acid.

The superabsorbent was ground so as to increase the quantity of suitably sized particles that fasten to the fibres and in order to investigate the possible influence on the absorption properties. The ground superabsorbent was screened to obtain a desired size distribution.

With the intention of adhering superabsorbent particles to the polymer fibre, a mixture of fibres and superabsorbent particles 30 was heated to a given temperature over a given period of time, more specifically to a temperature of 140°C over a time period of 10 min.

A series of tests was carried out on different fractions of 35 superabsorbent particles with the intention of studying the appearance of the fibres and to determine the quantities in which the absorbent had bonded to the fibres. Fractions of sizes 300-500 µm, 150-300µm, 90-150 µm and 38-90 µm were investigated. The tested fibre was an EAA-fibre.

In the case of the smallest superabsorbent fraction, 38-90 µm, the amount of superabsorbent that bonded to the fibre corresponded to 0.38 times the weight of the fibre. This factor is calculated in accordance with the following:

$$5 \quad K_{SF} = \frac{m_{SF} - m_f}{m_f}$$

where K_{SF} = index for the amount of bonded super-absorbent
 10 m_f = weight of fibre without superabsorbent
 m_{SF} = weight of fibre with bonded superabsorbent.

In the case of the next fraction, 90-150 µm, the amount of superabsorbent that bonded to the fibre corresponded to 2.46
 15 times the weight of the fibre. In the case of the fractions 150-300 µm, the amount of bonded superabsorbent corresponded to 6.4 times the fibre weight, while in the case of the largest fraction, 300-500 µm, the amount of superabsorbent that bonded to the fibre corresponded to 16.6 times the fibre weight. Figures 1
 20 and 2 are enlarged photographic views of an EAA-fibre with bonded superabsorbent particles of the size fraction 90-150 µm and 150-300 µm respectively.

By way of comparison, unscreened and unground superabsorbent has
 25 been bonded to an EAA-fibre, the amount of superabsorbent binding to the fibre corresponding to 13.3 times the weight of said fibre.

EVA-fibres were also coated with a superabsorbent from the size
 30 fraction 90-150 µm at the same temperature, 140°C for 10 min, resulting in roughly the same amount of bound superabsorbent as in the case of the EAA-fibre, i.e. 2.17 times the fibre weight.

Tests were also carried out in which the fibre was coated with
 35 superabsorbents of the same size fraction but while applying other temperatures. The fraction used was the 90-150 µm fraction and the fibres were EAA-fibres. When heating to a temperature of 110°C, the amount of superabsorbent that bonded to the fibres corresponded only to 0.26 times the fibre weight, despite ex-

tending the treatment time to 30 minutes. Only a small part of the fibre surface area was coated with superabsorbent. When heating to a higher temperature, 170°C for 10 min, the amount of bonded superabsorbent was 2.7 times the fibre weight.

5

At higher temperatures, and noticeably at 170°C, the superabsorbent particles not only bond to the fibre, but also to one another and form large agglomerates. This problem is greatly reduced when using unground superabsorbent, which is probably 10 because the superabsorbent particles exhibit a hydrophobic surface modification which disappears when grinding the superabsorbent.

Thus, the amount of superabsorbent that binds to the fibres 15 depends on heating temperature and particle size. The temperature would appear to be of little significance after having reached a sufficiently high temperature for the whole of the fibre surface to start binding superabsorbent. This occurs when the crystalline melting point of the fibre has been exceeded.

20

When admixing fibres with the adhesive superabsorbent particles in a cellulose fibre structure, no free particles that had fallen through the structure could be observed. Whether or not sufficient adhesion has been achieved can also be determined by 25 extending the fibre to twice its length for instance and checking whether or not all superabsorbent particles are still bonded to the fibre.

Absorption measurements

30

1. The tea bag method

Dip absorption for the two components and for the finished fibre with superabsorbent particles bound thereon was measured by the 35 tea bag method. According to this method, the sample is placed in a bag measuring about 5 x 5 cm and the bag is then sealed around its perimeter. The bag is then placed in a dish with an excess of 0.9% sodium chloride solution and the sample is allowed to swell freely in the bag. The amount of sample present

should not cause absorption to be restricted by the size of the bag. The sample is removed from the salt solution at given time points and allowed to drain for one minute and is then weighed. Upon completion of the measuring process in total, the bag is 5 centrifuged at 1.5 g for 10 min, whereafter the bag is weighed to provide a retention value, i.e. a value of the ability of the sample to retain the absorbed liquid under pressure.

Absorption can be calculated from the weight of the bags in 10 accordance with the following formula:

$$A_s = \frac{m_m - m_b (1+A_b) - m_s}{m_s}$$

15

where A_s = sample absorbency

A_b = tea bag material absorbency

m_m = weight of tea bag with sample after
absorption

20 m_b = weight of empty, dry tea bag

m_s = weight of dry sample.

The retention has been calculated as the absorbency after centrifugation, divided by absorbency prior to centrifugation. The 25 calculation has been made on the mean value of four bags in a sample series.

When measuring free fibres, a sample weight of about 0.1 g per bag was used, which is slightly more than one fifth of the 30 weight of the bag. A sample weight of about 0.2 g per bag was used for the superabsorbent. Measurements on fibres having bonded superabsorbent particles were made with a sample size based on the amount of bonded superabsorbent. This sample size was about 0.1 g per bag. The size fraction used was 90-150 μm . 35 The results of these measurements are reported in Table 1 below.

Table 1

	Sample	Abs. after 1 min g/g	Abs. after 5 min g/g	Abs. after 30 min g/g	Abs. after 60 min. g/g	Reten- tion %
5	EAA-fibre	18.8	15.8	16.7	17.8	0
	EVA-fibre	17.4	17.6	16.2	16.0	0
10	Screened unground superabsorbent	39.9	42.1	41.6	41.4	56
	Screened ground superabsorbent	50.3	53.2	52.3	52.1	68
15	Screened ground superabsorbent heated to 140°C for 10 min.	51.4	52.6	52.0	52.0	68
	Screened ground superabsorbent heated to 170°C for 10 min	51.0	51.5	50.9	51.0	69
20	EAA-fibre with bonded superabs. produced at 140°C for 10 min.	40.0	40.1	39.8	39.4	62
	EAA-fibre with bonded superabs. produced at 170°C for 10 min.	39.8	40.7	40.2	40.0	62
25	EVA-fibre with bonded superabs. produced at 140°C for 10 min.	40.7	39.5	38.8	38.9	60

In order to evaluate the absorption of the prepared fibres with superabsorbent particles fastened thereon, a comparison absorbency value has been calculated from the absorption of the fibres and absorbent. This value has been calculated in accordance with the following:

$$A_t = v_f A_t + v_{SAP} A_{SAP}$$

where A_t = the theoretical comparison absorbency value

v_f = the absorbency of the fibre

A_{SAP} = the absorbency of superabsorbent particles of the same size fraction and the same thermal history

v_f = the fibre weight fraction

v_{SAP} = superabsorbent weight fraction

This calculated value was then compared with the absorption value A_s , which was calculated from the weight of the total sample as beforementioned. This comparison is included in Table 2 below.

Table 2 Experimental and theoretical absorption values

25

		1 min g/g	5 min g/g	30 min g/g	60 min g/g	Retention %
EVA 140°C	$v_{SAP}=0,6826$	A,	40,7	39,5	38,8	38,9

	$v_f=0,2656$	A_t	42	42	42	42

35

2. Demand wetting

Absorbency under load was measured with the aid of a so-called demand wetting method. The sample is subjected to load from 5 above and the liquid allowed to penetrate up in the sample through a glass filter on which the sample rests. The upper surface of the glass filter is positioned on a higher level than the surface of the reservoir, with which the liquid communicates, so as to obtain a negative hydrostatic pressure. The 10 liquid used was a 0.9 % by weight sodium chloride solution and the negative pressure was 0.2 kPa. The sample load was applied cyclically at 10 min intervals. The load was 7.5 kPa during the first interval, 0.57 kPa during the second interval and again 7.5 kPa during the last interval. The sample body was a 5 mm 15 thick plate having a diameter of 50 mm and comprised of air-laid cellulose fluff.

Absorption under load was measured on sample bodies in the form of a fibre network. Measurements were made on four mutually 20 different samples: pure cellulose, cellulose air-mixed with superabsorbent particles of size fraction 90-150 μm , cellulose air-mixed with fibres having bonded thereto superabsorbent particles of the same size fraction as the free particles and cellulose with a layer of the same fibres as those above. The 25 cellulose fibres were CTMP-fluff and the fibre used was EAA-fibre produced at 140°C over a period of 10 min.

Figure 3 shows the amount of salt solution absorbed as a function of time in respect of two different samples, one consisting of cellulose fibres air-mixed with free superabsorbent particles, and one consisting of cellulose fibres air-mixed with fibre-bonded superabsorbent. The upper curve applies to cellulose having free superabsorbent particles, while the bottom curve applies to cellulose having fibre-bonded superabsorbent 30 particles. The load on the sample was lowered from 7.5 kPa to 0.57 kPa after 10 min and was raised again to 7.5 kPa after 20 min. The curve representing fibres having fibre-bonded superabsorbent particles in a fluff layer was about 1.5 ml beneath the 35

curve representing the sample with air-mixed fibre. These values are not shown in Figure 3.

Study of the absorption process

5

The course followed by the actual absorption process has been studied by allowing a fibre to absorb water droplets from one end while recording the process on a video film with the aid of a microscope. The droplets wet the superabsorbent and spread 10 over the length of the fibre, see Figure 4, whereafter a gel is formed, Figure 5. Figure 6 shows the fibre after a much larger amount of solution has been absorbed. When the fibre is allowed to dry in air, the superabsorbent particles will dry and release their bond with the fibre, as shown in Figure 7.

15

All photographs, Figures 4-7, show an EAA-fibre with bonded superabsorbent particles of size fraction 90-150 µm produced at 140°C for 10 min. EVA-fibres have also been studied in the same way and with the same results.

20

The bond between superabsorbent particles and fibres is broken in the process of absorption. This means that the absorbancy of the superabsorbents when swelling freely is not influenced by being bonded to a fibre, which is also shown by the aforesaid 25 absorption calculated from the absorption of the superabsorbent and the fibre. Absorption measurements taken with the aid of the demand wetting method show that samples which included fibre-bonded superabsorbent particles absorbed liquid at a slightly slower rate than samples that contained free particles. This is 30 probably because the fibres containing superabsorbents enlarge the pores of the fibre network, causing slower absorption in the sample.

In order for the superabsorbent particles to loosen as liquid is 35 absorbed, the use of permanent bonds shall be avoided so that as the superabsorbents swell the liquid or the force thus generated will cause the superabsorbent particles to loosen from the fibre. In that way gel blocking is prevented. Examples of app-

ropriate bonds are different types of physical (van der Waal's-forces) and ionic bonds.

The physical bonds shall be capable of providing good adhesion
5 between fibre and superabsorbent particles. In the examples
described above, acid-based interaction has been utilized,
together with the possibility of dimer formation between acrylic
acid groups. Diffusion of molecular chains over the boundary
surface or interface between fibre and superabsorbent also con-
10 tributes towards adhesion, although it should be limited so as
not to prevent the superabsorbent particles from loosening after
absorption.

The fibre polymer shall wet the superabsorbent particles so as
15 to achieve good contact. The contact angle θ between the polymer
melt and the superabsorbent particle will preferably be lower
than 90° .

In those tests reported in the foregoing, fibres of the co-
20 polymers EAA and EVA have been used. It will be understood,
however, that other thermoplastic fibres can be used, such as
polyolefins, e.g. polyethylene, polypropylene etc. Bicomponent
fibres having a core, e.g. of polyester or polypropylene and a
casing, e.g. of polyethylene, which has a lower crystalline
25 melting point than the core material, are also useful.

The invention can also be applied on nonwoven material in which
at least some of the fibres included are comprised of thermo-
plastic polymer fibre of the aforesaid kind. The superabsorbent
30 particles are fastened to the fibres in the nonwoven material in
a manner corresponding to that used in the case of loose fibres,
i.e. the nonwoven material is heated to a temperature at which
the superabsorbent particles will adhere to the thermoplastic
fibres in the material. The thermoplastic fibres are preferably
35 comprised of bicomponent fibres, although other thermoplastic
fibres can also be used.

The term superabsorbent particles shall be given a relatively
wide interpretation in the present context and shall be con-

sidered to include superabsorbent grains, granules, flakes and short fibres. The chemical composition of the superabsorbent may also be varied, and any particulate superabsorbent that has been found to possess absorption properties suitable for the present 5 purpose may be used. Mixtures of different superabsorbents may, of course, be used.

Figures 8 and 9 illustrate schematically two exemplifying embodiments of absorbent bodies 1 or the layers of absorbent 10 bodies intended for such absorbent articles as diapers, sanitary napkins, incontinence guards and the like. In the example shown in Figure 8, superabsorbent fibres 2 according to the invention are mixed with other fibres 3, for instance cellulose fibres. The superabsorbent fibres 2 and the cellulose fibres 3 can be 15 mixed and shaped to an absorbent body, for instance by a conventional air laying process. In the example illustrated in Figure 9, the superabsorbent fibres 2 are applied in the form of a layer between a surrounding layer of other fibres 3, for instance cellulose fibres. In this case, it is conceivable that 20 the fibres 2 are bound to one another and form a nonwoven material. The surrounding fibre layers 3 may alternatively consist of tissue layers.

Localization of the superabsorbent fibres 2 in the absorbent 25 body may be varied so that some parts of the absorbent body will contain a greater percentage of superabsorbent fibres than other parts of the body. The inventive superabsorbent fibres 2 may also be combined with other superabsorbents.

CLAIMS

1. A superabsorbent fibre or nonwoven material, characterized in that the fibre or at least a part of the fibres in the nonwoven material is/are comprised of thermoplastic polymeric fibre to which solid particles of superabsorbent material have been thermobonded by heating the polymeric fibre to a temperature at which adhesion is achieved between fibre and particles.
2. A fibre or nonwoven material according to Claim 1, characterized in that the thermoplastic polymeric fibre is at least partially comprised of a crystalline material and has a crystalline melting point not higher than 300°C, preferably not higher than 270°C.
3. A fibre or nonwoven material according to Claim 1, characterized in that the thermoplastic fibre consists of an amorphous material having a softening temperature not higher than 100°C.
4. A fibre or nonwoven material according to Claim 2 or 3, characterized in that the thermoplastic polymeric fibre is a polyolefin, for instance polyethylene or polypropylene, a polyester or a polyamide.
5. A fibre or nonwoven material according to Claim 2 or 3, characterized in that the thermoplastic polymeric fibre is a bicomponent fibre.
6. A fibre or nonwoven material according to Claim 2 or 3, characterized in that the thermoplastic polymeric fibre is a copolymer of ethylene and acrylic acid or methacrylic acid, or a copolymer of ethylene and vinyl acetate.
7. A fibre or nonwoven material according to one or more of the preceding claims, characterized in that the particles have a mean particle size smaller than 500 µm.

8. A method of producing a superabsorbent fibre or nonwoven material according to Claim 1, characterized by bringing solid particles of superabsorbent material into contact with a thermoplastic polymeric fibre or a nonwoven material that contains a thermoplastic fibre, said fibre being heated or having been heated to a temperature at which the superabsorbent particles will adhere to the fibre, and then permitting the mixture to cool.
- 5
- 10 9. A method according to Claim 8, characterized by heating the fibre to a temperature which exceeds the crystalline melting point of the fibre in case the thermoplastic fibre is at least partially comprised of a crystalline material.
- 15 10. A method according to Claim 8, characterized by heating the fibre to a temperature above its softening temperature in case the thermoplastic fibre is comprised of an amorphous material.
- 20 11. An absorbent article such as a diaper, sanitary napkin, incontinence guard and the like, characterized in that it includes at least one absorption layer (1) comprising superabsorbent fibres (2) or nonwoven material according to one or more of Claim 1-7.
- 25 12. An absorbent article according to Claim 11, characterized in that the superabsorbent fibres (2) are mixed with other fibres (3), for instance with cellulose fibres.
- 30 13. An absorbent article according to Claim 11, characterized in that the superabsorbent fibres (2) or the nonwoven material are/is applied in a layer between layers of other fibres (3) for instance cellulose fibres or between tissue layers.

Minimum documentation searched (classification system followed by classification symbols)

IPC6: A61L, A61F

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

SE, DK, FI, NO classes as above

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

WPI, CA, EPODOC, PAJ

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	WO, A1, 9110413 (WEYERHAEUSER COMPANY), 25 July 1991 (25.07.91), page 3, line 12 - line 18; page 4, line 16 - line 24; page 11, line 19 - line 32, the claims --	1-13
A	WO, A1, 9011181 (WEYERHAEUSER COMPANY), 4 October 1990 (04.10.90), page 7, line 13 - page 8, abstract, claims --	1-13
A	EP, A2, 0273141 (HANFSPINNEREI STEEN & CO. GMBH), 6 July 1988 (06.07.88), column 4, line 21; column 5, line 13, abstract, claims -- -----	1-13

 Further documents are listed in the continuation of Box C. See patent family annex.

- * Special categories of cited documents
- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed
- "T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- "X" document of particular relevance: the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- "Y" document of particular relevance: the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
- "&" document member of the same patent family

Date of the actual completion of the international search 21 December 1994	Date of mailing of the international search report 09 -01- 1995
Name and mailing address of the ISA/ Swedish Patent Office B x 5055, S-102 42 STOCKHOLM Facsimile No. +46 8 666 02 86	Authorized officer Sofia Nikolopoulou Telephone No. +46 8 782 25 00
